

## 5. Events

There are 4 events, that are fired by the API during the execution of the [AddSignature](#) function. All of them must be handled by the client application or the API will not be able to add a signature to a document. If you want to work with documents in read-only mode, e.g. check signatures or decrypt biodata, but don't want to add new signatures, then it's not necessary to provide event handlers.
